

Rec'd PCT/PTO 23 MAR 2005

Process for producing Vitamin C

The present invention relates to a process for producing L-ascorbic acid (vitamin C) from L-sorbose utilizing an aldehyde dehydrogenase, i.e., L-sorbose dehydrogenase, purified from the cell free extract of *Gluconobacter oxydans* DSM 4025 (FERM BP-3812).

5 The above mentioned enzyme was disclosed in EP 0 922 759 A2 and catalyzes the oxidation reaction of L-sorbose to 2-keto-L-gulonic acid (2-KGA).

Vitamin C is a very important and indispensable nutrient factor for human beings. It is industrially synthesized by the "Reichstein method". D-glucosone and L-sorbose are putative intermediates of vitamin C biosynthesis in bean and spinach, and the
10 nicotinamide adenine dinucleotide phosphate (NADP)-dependent enzyme catalyzing the oxidation reaction of L-sorbose to vitamin C has been partially purified. However, there have been no reports on the conversion of L-sorbose to vitamin C by using the enzyme originating from a bacterial source. Surprisingly, it was found that this enzyme can convert L-sorbose not only to 2-KGA, but also to vitamin C under specific
15 reaction.

The present invention provides a process for producing vitamin C from L-sorbose comprising contacting L-sorbose with a purified L-sorbose dehydrogenase having the following physico-chemical properties:

- (a) Molecular weight: $150,000 \pm 6,000$ Da or $230,000 \pm 9,000$ Da (consisting of 2 or 3
20 homologous subunits, each subunit having a molecular weight of $75,000 \pm 3,000$ Da);
- (b) Substrate specificity: active on aldehyde compounds;
- (c) Cofactors: pyrroloquinoline quinone and heme c;
- (d) Optimum pH: 6.4 to 8.2 for the production of vitamin C from L-sorbose;
- 25 (e) Inhibitors: Co^{2+} , Cu^{2+} , Fe^{2+} , Ni^{2+} , Zn^{2+} , monoiodoacetate and ethylenediamine tetraacetic acid;

in the presence of an electron acceptor, and isolating the resulting vitamin C from the reaction mixture.

For the purpose of the present invention, the term "purified" also includes isolated
30 from its natural environment.

- 2 -

Oxidation of L-sorbose to vitamin C in the presence of an electron acceptor occurs according to the following reaction equation:

The enzyme does not work with oxygen as an electron acceptor. In addition
5 nicotineamide adenine dinucleotide (NAD) and nicotineamide adenine dinucleotide phosphate (NADP) are not suitable electron acceptors. However, other conventional electron acceptors can be utilized in conjunction with the process of this invention. (2,6-dichlorophenolindophenol (DCIP), phenazine methosulfate (PMS), ferricyanide and cytochrome *c* are preferred electron acceptors.

10 The enzyme assay may be performed as follows:

a) Product (vitamin C) assay of L-sorbose dehydrogenase activity

A reaction mixture consisting of 1.0 mM PMS, 25 mM potassium phosphate buffer (pH 7.0), 1.0 μ M pyrroloquinoline quinone (PQQ), 1.0 mM CaCl_2 , 50 mM L-sorbose and enzyme solution in a final volume of 100 μ l with water is prepared just before the
15 assay. The reaction is carried out at 30°C for 60 min unless otherwise stated. The amount of vitamin C produced is measured at a wavelength of 264 nm by a high performance liquid chromatography (HPLC) which is coupled with a UV detector (TOSOH UV8000; TOSOH Co., Kyobashi 3-2-4, Chuo-ku, Tokyo, Japan), a dual pump (TOSOH CCPE; TOSOH Co.), an integrator (Shimadzu C-R6A; Shimadzu Co.,
20 Kuwahara-cho 1, Nishinokyo, Chukyo-ku, Kyoto, Japan) and a column (YMC-Pack Polyamine-II, YMC, Inc., 3233 Burnt Mill Drive Wilmington, NC 28403, U.S.A.). The amount of 2-KGA produced is measured by HPLC. One unit of the enzyme activity is defined as the amount of the enzyme that produces 1 mg vitamin C or 2-KGA in 60 min in the reaction mixture.

25 b) Photometrical assay of L-sorbose dehydrogenase activity

A reaction mixture consisting of 0.1 mM DCIP, 1.0 mM PMS, 50 mM potassium phosphate buffer (pH 7.0), 1.0 μ M PQQ, 2.0 mM L-sorbose and enzyme solution in a final volume of 100 μ l with water is prepared just before the assay. The reaction is started
30 at 25°C with L-sorbose, and the enzyme activity is measured as the initial reduction rate of DCIP at 600 nm. One unit of the enzyme activity is defined as the amount of the enzyme catalyzing the reduction of 1 μ mole DCIP per minute. The extinction coefficient of DCIP at pH 7.0 is taken as 14.2 mM^{-1} . A reference cuvette contains all the above constituents except of L-sorbose.

The L-sorbose dehydrogenase of the present invention can be isolated from a cell free extract of *G. oxydans* DSM 4025 (FERM BP-3812) in accordance with the methods described in EP 0 922 759 A2.

5 Thus, the present invention provides a process for producing vitamin C from L-sorbose as described above, wherein the L-sorbose dehydrogenase is derived from the strain *Gluconobacter oxydans* DSM 4025 (FERM BP-3812), a microorganism belonging to the genus *Gluconobacter* having the identifying characteristics of *G. oxydans* DSM 4025 (FERM BP-3812) or mutants thereof.

10 *G. oxydans* DSM 4025 was deposited at the Deutsche Sammlung von Mikroorganismen und Zellkulturen (DSMZ) in Göttingen (Germany), based on the stipulations of the Budapest Treaty, under DSM No. 4025 on March 17, 1987. The depositor was The Oriental Scientific Instruments Import and Export Corporation for Institute of Microbiology, Academia Sinica, 52 San-Li-He Rd., Beijing, Peoples Republic
15 of China. The effective depositor was said Institute, of which the full address is The Institute of Microbiology, Academy of Sciences of China, Haidian, Zhongguancun, Beijing 100080, People's Republic of China.

A subculture of the strain has also been deposited at the National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba Central 6, 1-1-1 Higashi,
20 Tsukuba, Ibaraki 305-8566, Japan, also based on the stipulations of the Budapest Treaty, under the deposit No. FERM BP-3812 on March 30, 1992. The depositor is Nippon Roche K.K., 6-1, Shiba 2-chome, Minato-ku, Tokyo 105-8532 Japan. This subculture is also most preferably used in the present invention.

The enzyme may be isolated and purified after the cultivation of the
25 microorganism, *G. oxydans* DSM 4025 (FERM BP-3812) as follows:
(1) Cells are harvested from the liquid culture broth by centrifugation or filtration.
(2) The harvested cells are washed with water, physiological saline or a buffer solution having an appropriate pH.
(3) The washed cells are suspended in the buffer solution and disrupted by means of a
30 homogenizer, sonicator or French press or by treatment with lysozyme and the like to give a solution of disrupted cells.
(4) The said enzyme is isolated and purified from the cell-free extract of disrupted cells, preferably from the cytosol fraction of the microorganism.

The enzyme applied to the process provided by the present invention is useful as a
35 catalyst for the production of vitamin C from L-sorbose. The reaction may be at pH

60°C for about 0.5 to 48 hours in the presence of an electron acceptor, for example DCIP, PMS and the like in a solvent such as phosphate buffer, Tris-buffer and the like. A pH of about 7.0 to 8.2 and a temperature in the range of from about 20°C to 50°C for about 0.5 to 24 hours are a condition under which L-sorbose is efficiently converted to vitamin C.

Thus, in the process of the present invention, the reaction is carried out at a pH of about 6.4 to about 9.0 and at a temperature of about 20°C to about 60°C for about 0.5 to about 48 h. A preferred reaction is carried out at a pH of about 7.0 to about 8.2 and at a temperature of about 20°C to about 50°C for about 0.5 to about 24 h.

The concentration of L-sorbose in a reaction mixture can vary depending on other reaction conditions but, in general, is about 0.5 to about 50 g/L, preferably from about 1 to about 30 g/L.

According to the present invention the catalytic reaction is carried out in water or aqueous solvents such as methanol, ethanol, acetone or mixtures of any one of these solvents and water, however, water is preferred from the view point of economy and easy handling.

In the process of this invention, the enzyme may also be used in an immobilized state with an appropriate carrier. Any means of immobilizing enzymes generally known in the art may be used. For instance, the enzyme may be bound directly to a membrane, granules or the like of a resin having one or more functional groups, or it may be bound to the resin through bridging compounds having one or more functional groups, for example glutaraldehyde.

The produced vitamin C in the reaction mixture may be isolated by conventional methods known in the art, and it may be separated as a salt, e.g., sodium, potassium, calcium, ammonium or the like. This salt may be converted into a free acid by conventional methods known in the art. Specifically, the separation may be performed by any suitable combination or repetition of the following steps: formation of a salt by using differences in properties between the product and the surrounding impurities, such as solubility, absorbability and distribution coefficient between the solvents, and absorption, for example, on ion exchange resin and the like. Any of these procedures alone or in combination constitutes a convenient means for isolating the product. The product thus obtained may further be purified in a conventional manner, e.g., by recrystallization or chromatography.

The following Examples further illustrate the present invention.

Example 1: Preparation of L-sorbose dehydrogenase

All the operations were performed at 8°C, and the buffer was 0.05 M potassium phosphate (pH 7.0) unless otherwise stated.

(1) Cultivation of *G. oxydans* DSM 4025 (FERM BP-3812):

- 5 *G. oxydans* DSM 4025 (FERM BP-3812) was grown on an agar plate containing 5.0% D-mannitol, 0.25% MgSO₄·7H₂O, 1.75 % corn steep liquor, 5.0% baker's yeast, 0.5% urea, 0.5% CaCO₃ and 2.0% agar at 27°C for 4 days. One loopful of the cells was inoculated into 50 ml of a seed culture medium containing 2% L-sorbose, 0.2% yeast extract, 0.05% glycerol, 0.25% MgSO₄·7H₂O, 1.75% corn steep liquor, 0.5% urea and
10 1.5% CaCO₃ in a 500 ml Erlenmeyer flask, and cultivated at 30°C with 180 rpm for one day on a rotary shaker.

- The cultured broth (10 ml) was transferred into 500 ml Erlenmeyer flasks containing 100 ml of the same seed culture medium and cultivated in the same manner as described above. The seed culture thus prepared was used for inoculating 15 liters of
15 medium, which contained 8.0% L-sorbose, 0.05% glycerol, 0.25% MgSO₄·7H₂O, 3.0% corn steep liquor, 0.4% yeast extract and 0.15% antifoam, in 30 L jar fermentor. The fermentation parameters were 800 rpm for the agitation speed and 0.5 vvm (volume of air/volume of medium/minute) for aeration at a temperature of 30°C. The pH was maintained at 7.0 with sodium hydroxide during the fermentation. After 48 h of
20 cultivation, 30 liters of the cultivated broth containing the cells of *G. oxydans* DSM 4025 (FERM BP-3812) by using the two sets of fermentors were harvested by continuous centrifugation. The pellets containing the cells were recovered and suspended in an appropriate volume of saline.

- After the suspension was centrifuged at 2,500 rpm (1,000 x g), the supernatant
25 containing the cells was recovered to remove the insoluble materials derived from corn steep liquor and yeast extract which were ingredients in the medium. The supernatant was then centrifuged at 8,000 rpm (10,000 x g) to obtain the cell pellet. As a result, 123 g of *G. oxydans* DSM 4025 (FERM BP-3812) cells (wet weight) was obtained from 30 liters of broth.

30 (2) Preparation of cytosol fraction:

The cell pellet (64.2 g) was suspended with 280 ml of the buffer and passed through a French pressure cell press. After centrifugation to remove intact cells, the supernatant was designated as the cell-free extract, and the cell-free extract was centrifuged at 100,000 x g for 60 min. The resultant supernatant (227 ml) was designated as the soluble fraction

- 6 -

of *G. oxydans* DSM 4025 (FERM BP-3812). After this fraction was dialyzed against the buffer, 150 ml of the dialyzed fraction having a specific activity of 0.107 unit/mg protein were used for the next purification step.

(3) Diethylaminoethyl (DEAE)-cellulose column chromatography:

5 The dialysate (150 ml) was put on a column of DEAE-cellulose (Whatman DE-52, 3 x 50 cm) equilibrated and washed with the buffer to elute minor proteins. Then proteins bound to the resin were eluted stepwise with 0.28, 0.32, 0.36 M NaCl in the buffer. Major enzyme activity was eluted at 0.36 M NaCl. The active fractions (143 ml) were collected.

10 (4) Carboxymethyl-cellulose column chromatography:

A portion (127 ml) of the active fraction from the previous step was filtrated by an ultrafiltrator (Centriprep-10, Amicon) to concentrate. After the concentrated sample (28 ml) was dialyzed against the buffer, 28 ml of the dialyzed fraction (31 ml) was put on a column of carboxymethyl-cellulose (Whatman CM-52, 3 x 23 cm) equilibrated with the
15 buffer. The proteins that passed through the column without binding to the resin were collected.

(5) Q-sepharose column chromatography (#1):

The pooled active fraction (43 ml) was concentrated by an ultrafiltrator (Centriprep-10). A portion (9.5 ml) of the concentrated fraction (10 ml) from the
20 previous step was put on a column of Q-sepharose (Pharmacia, 1.5 by 50 cm) equilibrated with the buffer. After the column was washed with the buffer containing 0.3 M NaCl, a linear gradient of NaCl from 0.3 to 0.6 M was added to the buffer. The active fractions were eluted at NaCl concentrations ranging from 0.55 to 0.57 M.

(6) Q-sepharose column chromatography (#2):

25 The pooled active fraction (22 ml) from the previous step was concentrated by an ultrafiltrator (Centriprep-10). The concentrate (3.0 ml) was dialyzed against the buffer. The dialyzed sample (3.5 ml) was put on a column of Q-sepharose (Pharmacia, 1.5 by 50 cm) equilibrated with the buffer. After the column was washed with the buffer containing 0.35 M NaCl, a linear gradient of NaCl from 0.35 to 0.7 M was added to the
30 buffer. The active fractions were eluted at NaCl concentrations ranging from 0.51 to 0.53 M.

(7) Gel filtration (Sephacryl S-300 High Resolution) column chromatography:

The pooled active fraction (20 ml) from the previous step was concentrated by an ultrafiltrator (Centriprep-10). A 1.5 ml portion of the concentrated and desalted (below 0.1 M NaCl) sample (2.0 ml) was put on a column of Sephacryl S-300 High Resolution (Pharmacia, 1.5 by 120 cm) equilibrated with the buffer containing 0.1 M NaCl. The active fractions (12 ml) were collected and dialyzed against the buffer.

(8) Hydrophobic column (RESOURCE ISO) chromatography:

The dialyzed active fraction from the previous step was concentrated by an ultrafiltrator (Centriprep-10). A portion (1.5 ml) of the concentrated sample (1.75 ml) was added to the equal volume (1.5 ml) of the buffer containing 3 M ammonium sulfate (final concentration: 1.5 M). After centrifugation (15,000 x g) of the sample, the supernatant was loaded on a column RESOURCE ISO (Pharmacia, 1.0 ml) equilibrated with the buffer containing 1.5 M ammonium sulfate. After the column was washed with the buffer containing 1.5 M ammonium sulfate, the proteins were eluted with the buffer containing a linear gradient of ammonium sulfate from 1.5 to 0.75 M. The active fractions corresponding to the L-sorbose dehydrogenase were eluted at ammonium sulfate concentrations ranging from 1.12 to 1.10 M. The active fractions were dialyzed against the buffer using dialysis cups (Dialysis-cup MWCO 8000, Daiichi pure chemicals). Afterwards, the fractions were collected and stored at -20°C. A summary of the purification steps of the enzyme is given in Table 1.

Table 1: Purification of the aldehyde dehydrogenase from *G. oxydans* DSM 4025 (FERM BP-3812)

Step	Total activity (units)	Total protein (mg)	Specific activity (units/mg protein)
Soluble fraction	343.0	3205.2	0.107
DEAE-Cellulose DE52	26.10	120.67	0.216
CM-Cellulose CM52	28.86	105.70	0.273
Q-Sepharose (#1)	38.94	12.56	3.100

RESOURCE ISO	3.71	0.12	31.71

Example 2: Influence of pH on the reaction products from L-sorbose

The reaction mixture consisting of the purified enzyme (0.42 µg), L-sorbose (50 mM), PMS (1 mM), CaCl₂ (1mM) and PQQ (1 µM) in 100 µl of 100 mM various buffers

was incubated for 1 h at 30°C. The reaction products were analyzed by thin layer chromatography (Silica gel 60F₂₅₄, MERCK) and HPLC. The vitamin C production was detected in the pH range from 6.4 to around 8.0. On the other hand, 2-KGA production was detected in the pH range from 5.4 to around 9.0 as shown in Table 2.

5 Table 2: Influence of pH on the reaction products from L-sorbose

Buffers used	pH set (-)	Vitamin C produced (mg/L)	2-KGA produced (mg/L)
Citrate-NaOH	4.4	0.0	0.0
	5.4	0.0	21.5
	6.4	6.5	5.1
Potassium phosphate	6.6	11.9	5.0
	7.1	29.0	not done
	7.4	48.8	9.6
	7.8	38.8	17.6
	8.2	21.0	24.8
Tris-HCl	7.9	19.5	92.3
	8.4	0.0	106.3
	8.9	0.0	147.5

Example 3: Effect of temperature on the activity

10 The reaction mixture containing 0.42 µg of the purified L-sorbose dehydrogenase, 50 mM L-sorbose, 1 µM PQQ, 1mM CaCl₂, 1 mM PMS in 25 mM potassium phosphate buffer (pH 7.0) was incubated for 60 min at various temperatures. L-sorbose was converted to vitamin C and 2-KGA as shown in Table 3.

Table 3: Effect of temperature on the conversion activity of L-sorbose to vitamin C and 2-KGA

Temperature (°C)	Vitamin C produced (mg/L)	2-KGA produced (mg/L)
20	148.6	36.1
25	111.1	32.6
30	115.9	34.4
35	107.8	30.3
40	141.4	35.4
50	111.4	41.5
60	6.4	20.6
